Phytoremediation of sewage pollutants through some macrophytes near industrial area of Balrampur

Received: 04-11-2009 Revised: 12-02-2010 Accepted: 28-03-2010

Abstract
The present study deals with the phytoremediation of aquatic pollutants through macrophytes including *Lemna*, *Eichornia* and *Hydrilla*. The study was conducted from June 2009 to September 2009 on Suawn Nala and was observed that application of aquatic plants is the cheapest and ecofriendly method for the removal of pollutant from sewage.

Keywords: Aquatic plants, Ecofriendly, Macrophytes, Phytoremediation, Sewage

Introduction
Balrampur is a fast developing industrial city at Indo-Nepal border at eastern Uttar Pradesh and is a famous industrial city and well known for a major sugar industry *i.e.* Balrampur Chini Mill (BCM) Ltd. BCM is the largest sugar industry of India by its production point of view. In spite of this unit several other small scale industries like pulse mill, rice mill, dairy plants etc. are also functional in Balrampur. These units are discharging their wastes and garbage into Suawn Nala, Balrampur (Fig.1). This is the fact that these industries are the backbone of the rural economy of Balrampur. Need has arisen to review and recognize environmental problems associated with them. The enormous quantities of wastes (solid, liquid, and gas) generated by these rural industries has led to problems of air, water, and soil pollution. The problems of water quality and water pollution are solely severe in many industrial areas and are threatening the population residing in adjoining areas. In the recent past, several studies (Manas, 1976; Kundra and Purthy,1979; Handa, 1981; Krupanidhi, 1984) have reported that receiving water bodies are becoming increasingly contaminated due to discharge of domestic and industrial waste waters. The present study deals with the phytoremediation of aquatic pollutants of Suawn Nala by some aquatic macrophytes *viz.* *Lemna*, *Eichornia* and *Hydrilla*. These plants have great potential in treating industrial effluent and to prevent early pollution of water bodies.

Materials and Method
Phytoremediation of polluted water of Suawn Nala, Balrampur was done by using macrophytes. A fresh plant of *Eichornia*, *Lemna* and *Hydrilla* having 100 g weight were grown in cemented turf of 60 cm diameter and 20 cm depth, containing polluted water of Suawn Nala for a period of 10 days. The treatment potential of the macrophytes and elimination of pollutants from polluted water of Suawn Nala were assessed on monthly basis by estimating quality of polluted water before and after treatment. The quality was determined by analyzing physico-chemical parameters following the standard methods of APHA (1998) and Khanna and Bhutiani (2008).

Results and Discussion
The result of physico-chemical analysis of polluted water of Suawn Nala, Balrampur City before and after 10 days of culture of *Eichornia*,

**Lemna** and **Hydrilla** are presented in Table 1. Reduction in the temperature was observed after 10 days of culture. The effect of temperature controls the chemical reactions, solubility of the substances, chemical and biological reaction of the organism in water and the growth of nuisance organisms are enhanced by warm water condition and could lead to the unpleasant taste and odour.

![Fig. 1: Suawn Nala- carrying industrial effluent](https://via.placeholder.com/150)

(Sacramento, 1963, Mechalas et al., 1972). In natural water, pH changes diurnally and seasonally due to variation in photosynthetic activity, which increases the pH value (Bouwer, 1978; Yadav et al., 1987). The pH value was observed around 7.0 before the culture but it increased after culture. The treated sewage showed effective reduction in turbidity. The values were in the range of 22 NTU-37.8 NTU. Electrical conductivity was in the range of 736.2 – 907 µmhos/cm. According to Rao et al. (1979), solids in water samples vary with the alkaline nature. Total alkalinity observed before the treatment was in the range of 285 – 327 mg/l which reduced after the treatment and was observed in the range of 254 – 293 mg/l. Free CO₂ was observed highest in the month of August i.e. 108 mg/l and was lowest in the month of September i.e. 2.9 mg/l, before and after treatment.

BP= Before Plantation, AP = After Plantation

Very small changes were reported in chloride content due to non-utilization by the plants. Dissolved oxygen (DO) values were increased in small quantity in sewage water after culture of *Eichornia, Lemna* and *Hydrilla* which helped in oxygen transfer in water system by their roots. Chemical oxygen demand (COD) was recorded maximum as 293.4 mg/l in the month of June and minimum was observed as 121.0 mg/l after treatment in the month of September. The reduction in COD after culture was due to more availability of oxygen in water for oxidation of organic matter. The peak value of total hardness (349 mg/l) was observed in the month of August.
Phytoremediation of sewage pollutants

Calcium value was always found above 100 mg/l in all the four months of experimentation. Calcium being a useful nutrient absorbed by plant *Eichornia*, *Lemna* and *Hydrila* for their growth and development which fluctuated from 103 to 167 mg/l before and after treatment in different months. Nitrogen content was estimated in the form of ammonical nitrogen. Nitrate nitrogen is the stable product of oxidation, the maximum value of nitrate nitrogen was observed 24.7 mg/l while minimum was observed as 5.50 mg/l before and after treatment. Phosphorus content was estimated as total phosphate. The peak value of phosphate was found as 0.502 mg/l and organic phosphates as 0.899 mg/l in the month of September.

The potential of *Eichornia*, *Lemna* and *Hydrila* species for phytoremediation of polluted water of Suawn Nala, Balrampur city was evidenced from the result of net primary productivity (NPP), which registered a significant increase in value after 10 days of culture. The higher value of NPP of *Eichornia* was observed 2.10 g.m⁻² day⁻¹ in month of August (Table 2) and the higher value of NPP of *Lemna* was observed 0.59 g.m⁻² day⁻¹ in month of August (Table 3). Like *Eichornia* and *Lemna*, in *Hydrila* the value of NPP was found maximum as 2.59 g.m⁻² day⁻¹ in the month of September (Table 4). The observed NPP value proved that rainy season is the best for phytoremediation of sewage water through *Eichornia*, *Lemna* and *Hydrila* species. The result of in vitro culture has proved the application of aquatic plant *Eichornia*, *Lemna* and *Hydrila* species for removal of pollutant from sewage water of Balrampur city (Dings, 1978). It is
concluded from the above findings that phyto remediation is the cheapest, ecofriendly and natural method for the removal of pollutant occur in sewage.
